Date:

10 july 2026

1. Introduction

This report covers a basic Python program that takes two numbers from the user and performs simple arithmetic and comparison operations, displaying the results with f-strings.

2. Program — Arithmetic and Comparison Operators

The program reads two numbers, calculates their sum, difference and product, checks whether the first number is greater than the second and whether the two numbers are equal, and prints all the results.

2.1 Code

```
num1 = float(input("Enter first number: "))
num2 = float(input("Enter second number: "))
sum_result = num1 + num2
difference = num1 - num2
product = num1 * num2
greater = num1 > num2
equal = num1 == num2
print(f"Sum: {sum_result}")
print(f"Difference: {difference}")
print(f"Product: {product}")
print(f"First number is greater: {greater}")
print(f"Numbers are equal: {equal}")
```

2.2 Sample Output

```
Enter first number: 8
Enter second number: 5
Sum: 13.0
Difference: 3.0
Product: 40.0
First number is greater: True
Numbers are equal: False
```

3. Explanation

The program uses two kinds of operators:

- Arithmetic operators (+, -, *) calculate the sum, difference and product.
- Comparison operators (> and ==) return a Boolean value — True or False.

float(input(...)) is used so the program accepts decimal numbers, which is why the results are shown with a decimal point (for example 13.0). The comparisons greater and equal produce Boolean results: with 8 and 5, "greater" is True and "equal" is False.

4. Conclusion

This program practised reading numeric input with float(), using arithmetic operators for calculations and comparison operators for Boolean results, and formatting output with f-strings. The program ran successfully and produced the expected results.
